July 3, Tuesday, 15:30

Section I

Experimental Investigations of Atomic Nucleus Properties

Klimochkina A.A.

Neutron radii of Ca and Zr isotopes near the neutron drip-line within the dispersive optical model. - 15 min. 59

Dyachkov V.V.

Modulation of angular distributions of scattered alpha particles by multicluster nuclei. - 15 min. 60

Izosimov I.N.

Structure of β -decay strength function $S_{\beta}(E)$ in halo nuclei. - 15 min. 61

Joint talk:

Collective states in ^{156}Dy . 62

Collective states in ^{158}Dy . 63

Reporter *Efimov A.D.* - 20 min.

Yushkov A.V.

Clusterization and crystallization of nuclei. - 15 min. 64

Novatsky B.G.

Search for light multineutrons in fission of ^{238}U induced by neutrons from the IR-8 reactor. - 15 min. 65

July 3, Tuesday, 15:30

Section II

Experimental Investigations of Nuclear Reactions Mechanisms

Zherebchevsky V.I.

Investigations of the nuclear reaction excitation functions with medical radionuclides which formed in the exit channels. - 15 min. 72

Avdeyev S.P.

Radial flow in the interaction of relativistic deuterons with a gold target. - 15 min. 73

Chudoba V.

Three-body correlations in ^6Be populated in (p,n) reaction. - 15 min. 74

Fedorov N.A.

Angular correlations in the 14.1 MeV neutrons inelastic scattering on Al. - 20 min. 75

Zuyev S.V.

Study of the possibility of using various aerosol filters in neutron activation analysis. - 15 min.

202

July 4, Wednesday, 17:00

Poster Session I

Section I

Experimental Investigations of Atomic Nucleus Properties

Bespalova O.V.

Evolution of the single-particle structure of neutron-rich isotones with $N = 20$ within the dispersive optical model.

66

Dyachkov V.V.

Investigation of cluster configurations of nuclei from ^{11}B to ^{209}Bi on α -particles beams.

67

Dyachkov V.V.

Modernization of the scattering camera on the U-400 beam for precision measurements of heavy multiclusters.

68

Kurguz I.V.

Structure and total strength of the magnetic dipole resonance on excited states in sd shell nuclei.

69

Kuterbekov K.A.

A new scattering chamber for conducting precision experiments on the heavy-ion reaction cross sections at the accelerator DC-60 (Astana, Kazakhstan) at low energies.

70

Vakhtel V.M.

Outliers in the sequences of counts of radiation flow particles.

71

Section II

Experimental Investigations of Nuclear Reactions Mechanisms

Erdemchimeg B.

Total reaction cross sections of neutron-rich light nuclei measured by the COMBAS fragment-separator.

103

Kurakhmedov A.

Investigation of $^{14}\text{N}+^{10}\text{B}$ nuclear reactions outputs at low energies.

104

Section IV

Nuclear Reactions Theory

D'yachenko A.T.

A non-equilibrium equation of state and emission of high energy particles in heavy ion collisions. 167

Ibraeva E.T.

Scattering of protons on carbon isotopes $^{9,13,15}\text{C}$ in the Glauber approximation. 168

Sandul V.S.

The influence of color reconnection and jet formation effects on charge particle transverse momentum distribution in p+p collisions at LHC energies. 169

Valiev F.F.

Generalized multipomeron exchange model. 170

Section V

Technique and Methods of Experiment and Applications of Nuclear-Physical Methods

Babicheva S.Yu.

Researching the synergetic effect using a radioactive beam in medicine via statistical simulation. 203

Burtebayev N.

Modification of activation method of the astrophysical S-factors measurement. 204

Buzoverya M.E.

Nuclear microprobe to be used as evaluator of cathode electrode degradation of cathode strip chamber prototype under CMS experiment. 205

Dvurechensky V.I.

Device for registration of the number of pulses and measuring of time intervals of radiation flows. 206

Dyachkov V.V.

Study of the factor of local accumulation of daughter products of radon decay in the body by the beta-spectrometry. 207

MODULATION OF ANGULAR DISTRIBUTIONS OF SCATTERED ALPHA PARTICLES BY MULTICLUSTER NUCLEI

Dyachkov V.V.¹, Dusebayeva K.S.¹, Akhmetzhanova M.M.²

In [1], for the first time, we explained the phenomenon of a significant excess of cross sections over Rutherford at small angles, which turned out to be a fragment of a simple diffraction pattern with oscillations $\Delta\theta_\alpha$ of a longer period than oscillations on the core-matrix $\Delta\theta_\alpha$ as a whole, that is, $\Delta\theta_\alpha > \Delta\theta_n$. This large period $\Delta\theta_\alpha$ turned out to be the first diffraction ring on intranuclear spatially isolated α -clusters. This explanation is reliable, since the existence of α -particle nuclear matter has been comprehensively investigated by us and, thus, proved earlier [2] on the basis of other experimental data.

In this work, a wide systematic of the modulation parameters of Fraunhofer oscillations on matrix nuclei from lithium to nickel with oscillations from the elastic scattering of incident α particles on intranuclear multicluster with masses from the proton to the α particle is carried out. Cluster widths, equivalent to the stats of multicluster, are taken from our work [3].

$$\sigma_{\text{tot}} N_{\text{tot}} = \sigma_0 N_0 + \sigma_1 N_1 + \dots + \sigma_n N_n$$

For the cluster widths of nuclei-matrix are unknown, these parameters were found by describing the experimental angular distributions of the differential cross sections for elastic scattering using the method proposed in [1].

For expansion of the list of the detected multicluster, NNDC databases of experimental angular distributions of the differential cross sections for elastic scattering with doubly magic nuclei with ^{16}O as incident particle were used.

Such incident particles made it possible to find multi-clusters in nuclei with masses from $A = 4$ to $A = 16$.

Thus, the phenomenon of modulation has been extended by us in this work for all the stat widths of all multicluster, which raises new questions to experimental methods increasing the accuracy of measuring the maximums of diffraction oscillations.

The discovery of two new kinematic methods of detection and investigation of intranuclear multicluster [1] with accurate registration of multicluster kinematics («kintracks») was surprisingly universal, unambiguous and reliable. The only limitations of the method are: 1) the probing particle must be twice magical so that its structure does not appear to be a perturbing factor for the structure of multicluster nuclei; 2) the path of the probing particle in the probed nuclear matter (in the nucleus-matrix) must be comparable or larger than the diameter of the nucleus -matrix, that is, the energy of the probing particle must be appropriately selected.

The experiments were performed on beam of 29 MeV α -particles at ^{11}B , ^{13}C , ^{24}Mg , ^{25}Mg , ^{59}Co , ^{120}Sn , ^{197}Au , and ^{209}Bi nuclei in the angular range from 10° to 89° in laboratory system. The aim of the measurements was to search for light multicluster with mass numbers from 1 to 4: p, d, ^3He , α in the indicated nuclei. In this case, we assume a nonzero probability of the existence of such multiclusters inside the volume of the investigated nuclei with the indicated mass numbers, which do not exist in the free state, but in the nucleus volume, in connection with the Heisenberg uncertainty relation, they have a finite probability for existence. To achieve this goal, two tasks were accomplished: 1) find the effect of «dissolution» of multiclusters with increasing mass number; 2) find the effect of «raising» of α -clusters that survived the dissolution process on the surface of the nucleus with increasing mass number.

As a result of systematic experimental studies, both effects have been found - the corresponding cluster widths have a trend toward a decrease in the transition to heavy nuclei. As for such «solid nuts» as nucleons and α -clusters, their survival in a medium with giant nuclear forces tearing loose multicluster into pieces means their high binding energy contributes to their survival. But, nevertheless, alpha-clusters are raised up to the surface by nuclear forces, giving rise to the phenomenon of alpha-radioactivity. The mass spectra of multiclusters are studied. The cluster widths θ_n^2 for them are introduced by us in the $N_0 = N_1 + N_2 + \dots + N_n$; $1 = \frac{N_1}{N_0} + \frac{N_2}{N_0} + \dots + \frac{N_n}{N_0} = \theta_1^2 + \theta_2^2 + \dots + \theta_{n1}^2$ form. It is shown that cluster widths decrease with increasing mass number. Effective numbers of clusters are found across the whole range of mass numbers. Both the widths and effective numbers confirmed the existence of the above new nuclear effects with exotic nuclei and clusters.

MODERNIZATION OF THE SCATTERING CAMERA ON THE U-400 BEAM FOR PRECISION MEASUREMENTS OF HEAVY MULTICLUSTERS

E-mail: slava_kpss@mail.ru

In experimental studies of multicluster parameters in nuclei, specific, rather stringent, requirements are imposed on the scattering chamber. First of all, this concerns the total angular resolution of the spectrometer of scattered particles, which consists of two components. The first component is the angular spread of the beam $\Delta\theta_k$, determined by the passive input collimator of the scattering chamber. It is regulated by the diameter of the input cutting diaphragm d_1 , the diameter of the output diaphragm d_2 and the distance between them (the base of the input collimator) L . Then the angular resolution of the input collimator will be determined by the formula $\Delta\theta_k = 2\arctg \frac{d_1+d_2}{2L}$.

The second component of the total angular resolution of the spectrometer is the geometric system «beam spot on the target (d_m) + input diaphragm of the particle detector (d_d)» and the distance between them (the base of the «target-detector» system) L_{md} . Especially note that it is the beam spot on the target that serves as the "input cutting diaphragm" for the imaginary (virtual) «collimator» of the particle detector. Then the angular resolution of the «target-detector» system will be determined by the formula $\Delta\theta_{md} = 2\arctg \frac{d_m+d_d}{2L_{md}}$.

A very important parameter in the attempt to achieve the minimum angular resolution of the spectrometer $\Delta\theta_{sp}$ is the distance from the output cutting diaphragm of the input passive collimator to the nuclear target l . Note that this parameter, as a rule, is often overlooked by many researchers. The formula for calculating the beam spot on the target has the form $d_m = d_2 + (d_1 + d_2) \frac{l}{L}$.

With the first measurements of Wulf-Bragg diffraction on quasicrystalline nuclei in the zinc region, we apparently used such a stiff collimation of the beam and the entire geometry of the experiment.

It should be noted that in the planning of experiments with good angular resolution, the use of slotted, square, rectangular and other forms of collimators is absolutely unacceptable. In all these cases, the angular resolution of the spectrometer is completely determined by the diagonal sizes of all these geometric figures.

THE INCLUSIVE CROSS SECTIONS FOR THE FORMATION OF p, d, α FROM THE INTERACTION OF α -PARTICLES OF 29 MeV ENERGY WITH NUCLEI ^{27}Al AND ^{59}Co

Obtaining new experimental nuclear data on double differential and integral cross sections of reactions initiated by stable isotopes of helium aimed at replenishing the information base is necessary for the design of the energy reactor safety systems and the development of promising nuclear technologies.

The experimental spectra of nuclear reactions on the ^{27}Al and ^{59}Co nuclei were obtained on an isochronous cyclotron U-150M (Kazakhstan). The energy of the incident ^4He ions was 29 MeV. Measurements are made in the angular range of $30^\circ - 135^\circ$ in the laboratory coordinate system with a step of 15° . As the target, ^{27}Al and ^{59}Co are selected, as structural elements and elements of the target node of the ADS being designed. Enriched foils of these isotopes were prepared, the thickness and uniformity of which was determined by measuring the energy loss of alpha particles from the ^{226}Ra isotope.

To measure the cross sections of the reactions, a standard $dE-E$ method was used, where two parameters of the detected particle are recorded: specific ionization and total energy. The energy calibration of the detectors is based on kinematics calculations within the framework of the LISE code. The analysis of the obtained experimental data is carried out within the framework of the PRECO-2006 [1] design code, which is based on modern theoretical models of nuclear decay.

The obtained experimental results fill the missing values of the cross sections of the reactions studied and can be used in the development of new approaches to the theory of nuclear reactions, as well as in the construction of hybrid nuclear power plants, in nuclear medicine.

STUDY OF THE FACTOR OF LOCAL ACCUMULATION OF DAUGHTER PRODUCTS OF RADON DECAY IN THE BODY BY THE BETA-SPECTROMETRY

Dyachkov V.V., Zaripova Yu.A., Yushkov A.V., Shakirov A.L.,
Bigeldiyeva M.T., Dusebayeva K.S., Abramov K.E.
National Nanotechnology Laboratory of Open Type, Almaty, Kazakhstan
E-mail: slava_kpss@mail.ru

During the life of any animal vegetable or microbial organism is a continuous accumulation of isotopes and radon daughter products (DPR) their decay [1, 2]. According to the ICRP, DPR are oncoradiogenerators of tumor diseases, therefore their identification in the body can be an effective means of early diagnosis of the oncological morbidity of the population.

The purpose of this work was the fundamental research of the mechanisms of formation of nanoscale oncorodigenic structures in the body and the development on this basis of anirac express devices for their detection.

Experiments have been performed to measure beta spectra in phantom samples of living organisms for a long time accumulating DPR. The Fig. 1 shows the spectrum of one of a series of similar measurements, from which it can be seen that indeed the accumulation effect exists and stands out well enough over the background. To implement the same measurements in the model of the express device, test measurements were carried out using CsI (TI) photonic amplifiers.

Fig. 1. The beta-radiation spectrum of the accumulated daughter products of the radon decay in the sample.

The work was supported by the state grant financing of basic research (project No. IRN AP05131884, No. IRN AP05133577).
